Framework

CPBPV

DPVS

FM Application

Discussion

Formal proof methods that ensure the *absence of all bugs* are **too expensive**, or require manual efforts

- **Automatic generation of counterexamples** violating a property on a limited model of the program is very useful
- **Challenge**: finding bugs for **realistic time periods** for **real time applications**

- ▶ **Mechanically check properties of models**
- ▶ Widely used in **hardware verification and software verification**
- ▶ Automatic generation of **counterexamples**

Basics on BMC

Motivations

BMC: overview

Algorithm

CP & BMC

The CP
Framework

CPBPV

DPVS

FM Application

Discussion

- ▶ **Models** → finite automates, labelled transition systems
- ▶ **Properties:**
 - ▶ **Safety** → something bad should not happen
 - ▶ **Liveness** → something good should happen
- ▶ **Bound k** → look only for counter examples made of k states

Algorithm for Model Checking Safety

% set of states: S , initial states: I , transition relation: T
% **bad states B reachable from I via T ?**

bounded_model_checker_{forward}(I, T, B, k)

$S_C = \emptyset; S_N = I; n = 1$

while $S_C \neq S_N$ **and** $n < k$ **do**

if $B \cap S_N \neq \emptyset$

then return **“found error trace to bad states”**;

else $S_C = S_N$;

$S_N = S_C \cup T(S_C)$;

$n = n + 1$;

done

return **“no bad state reachable”**;

BMC: Bounded Model Checking

- BMC: falsification of a given property is checked for a given **bound**
- BMC mainly involves three steps:
 1. the **program is unwound k** times,
 2. the unwound program and the property are translated into **a big propositional formula ϕ**
 ϕ is satisfiable iff there exists a counterexample of depth less than k
 3. **A SAT-solver or SMT-solver** is used for checking the satisfiability of ϕ

Discussion

CP-based Bounded Program Verification

- CP-based BMC: falsification of a given property is checked for a given **bound**
- CP-based BMC mainly involves three steps:
 1. the **program is unwound k** times,
 2. An annotated and simplified **CFG** is built
 3. Program is translated in constraints **on the fly**

A **list of solvers** tried in sequence (LP, MILP, Boolean, CP)

Basics on BMC

The CP
Framework

Overall view

Pre-processing

A small example

Language and
restrictions

Constraint store

Scalar assignment

Array assignment

Conditional instruction
while instruction

CPBPV

DPVS

FM Application

Discussion

▶ CP framework

- Specification → constraints
Program → constraints (**on the fly**)
- Solving Process
 - **List of solvers** tried in sequence
on **each selected node of the CFG**
 - Takes advantage of the **structure** of the program

▶ BMC based on SAT / SMT solvers

- Program & specification → **Big Boolean formula**
- Solving Process
 - SAT solvers or SMT solvers (SAT solvers
& specialised solvers)
 - ↪ **spurious solutions** → **backtracks**
 - Critical issue: **minimum conflict sets**

Pre-processing

1. P is **unwound k times** $\rightarrow P_{UW}$
2. $P_{UW} \rightarrow DSA_{P_{UW}}$, **Dynamic Single Assignment form**
(each variable is assigned exactly once on each program path)
3. $DSA_{P_{UW}}$ is **simplified according to the specific property $prop$** by applying slicing techniques
4. Domains of all variables are filtered by **propagating constant values** along G , the simplified CFG

Discussion

A small example(continued)

Initial CFG

```
void foo(int a, int b)
```

```
int c, d, e, f;
```

```
if(a >= 0) {
```

```
    if(a < 10) {f = b - 1;}
```

```
    else {f = b - a; }
```

```
    c = a;
```

```
    if(b >= 0) {d = a; e = b;}
```

```
    else {d = a; e = -b; } }
```

```
else {
```

```
    c = b; d = 1; e = -a;
```

```
    if(a > b) {f = b + e + a;}
```

```
    else {f = e * a - b; } }
```

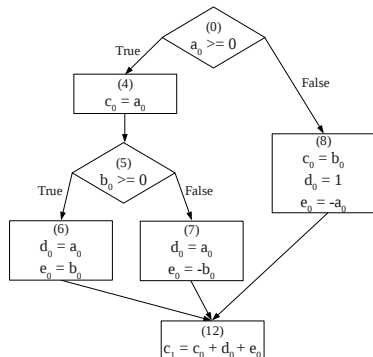

```
c = c + d + e;
```

```
assert(c >= d + e); // property p1
```

```
assert(f >= -b * e); // property p2
```

A small example(continued)

Simplified CFG

```
void foo(int a, int b)
```

```
int c, d, e, f;
```

```
if(a >= 0) {
```

```
if(a < 10) {f = b - 1;}
```

```
else {f = b - a;}
```

```
c = a;
```

```
if(b >= 0) {d = a; e = b;}
```

```
else {d = a; e = -b;}
```

```
else {
```

```
c = b; d = 1; e = -a;
```

```
if(a > b) {f = b + e + a;}
```

```
else {f = e * a - b;}
```

```
c = c + d + e;
```

```
assert(c >= d + e); // property p1
```

```
assert(f >= -b * e); // property p2
```

CPBPV

DPVS

FM Application

Discussion

- ▶ **Java** programs and **JML** specifications

JML =

- Comments in java code (“javadoc” like)
(can be compiled and executed at run time)
- Properties are directly expressed on the **program variables**
→ no need for abstraction
- Pre-conditions and post-relations
- **Exists** and **Forall** quantifiers

- ▶ **C** programs and **assertions**

Constraint store

Scalar assignment

Array assignment

Conditional instruction

while instruction

CPBPV

DPVS

FM Application

Discussion

- ▶ **Unit code** validation
- ▶ Data types : integers, arrays of integers
- ▶ **Bounded programs** : array lengths, number of unfoldings of loops, size of integers are known
- ▶ Normal behaviours of the method (no exception)
- ▶ JML specification :
 - post condition : the conjunction of use cases of the method
 - possibly a precondition

Basics on BMC

The CP
Framework

Overall view

Pre-processing

A small example

**Language and
restrictions**

Constraint store

Scalar assignment

Array assignment

Conditional instruction

while instruction

CPBPV

DPVS

FM Application

Discussion

- ▶ Each **expression** is mapped to a **constraint**:
 ρ transforms program expressions into constraints
- ▶ SSA-like **variable renaming**: $\sigma[\mathbf{v}]$ is the current renaming of variable \mathbf{v}
- ▶ JML :
 - $\backslash \mathbf{forall\ i} \rightarrow$ conjunction of conditions
 - $\backslash \mathbf{exist\ i} \rightarrow$ disjunction of conditions

(\mathbf{i} has bounded values)

Constraint store

Scalar assignment

Array assignment

Conditional instruction

while instruction

CPBPV

DPVS

FM Application

Discussion

► array assignment

$$\sigma_2 = \sigma_1[a/\sigma_1(a) + 1]$$

$$c_2 \equiv (\rho \ \sigma_2 \ a)[\rho \ \sigma_1 \ e_1] = (\rho \ \sigma_1 \ e_2)$$

$$c_3 \equiv \forall i \in 0..a.length(\rho \ \sigma_1 \ e_1) \neq i \rightarrow (\rho \ \sigma_2 \ a)[i] = (\rho \ \sigma_1 \ a)[i]$$

$$\frac{}{\langle [a[e_1] \leftarrow e_2, l], \sigma_1, c_1 \rangle \mapsto \langle [l], \sigma_2, c_1 \wedge c_2 \wedge c_3 \rangle}$$

Program (a.length=8)

`a[i] = x;`

Constraints

$\{a_1[i_0] = x_0, i_0 \neq 0 \rightarrow a_1[0] = a_0[0],$
 $i_0 \neq 1 \rightarrow a_1[1] = a_0[1], \dots, i_0 \neq 7 \rightarrow a_1[7] = a_0[7]\}$

guard \rightarrow *body* is a **guarded constraint**

$a[i] = x$ is the **element constraint**: i and x are constrained variables whose values may be unknown

Implementation

Experiments

DPVS

FM Application

Discussion

- ▶ Translate precondition of the specification (if it exists) into a set of constraints **PRECOND**
- ▶ Translate post condition of the specification into a set of constraints **POSTCOND**
- ▶ Explore **each branch** B_i of the program and translate instructions of B_i into a set of constraints **PROG_Bi**

Basics on BMC

The CP
Framework

CPBPV

Overall view

Example

Implementation

Experiments

DPVS

FM Application

Discussion

- ▶ For each branch B_i , solve $\text{CSPI} = \text{PROG_Bi} \wedge \text{PRECOND} \wedge \text{NOT}(\text{POSTCOND})$
 - If for each branch B_i **CSPI is inconsistent**, then the program is **conform** with its specification
 - If for a branch B_i **CSPI has a solution**, then this solution is a **test case** which illustrates a **non-conformity**
- ⚠ **Inconsistencies of CSPI** are detected at **each node** of the control flow graph

Discussion

► **Conditional**

```
if (t[m]==v) return m;
```

$t_0[m_0] = v_0$ is consistent with the constraint store
so take the if part

$CSP \leftarrow CSP \wedge t_0[m_0] = v_0$

► Complete execution path p whose constraint store
 C_p is:

$C_{pre} \wedge l_0 = 0 \wedge u_0 = 7 \wedge m_0 = 3 \wedge t_0[m_0] = v_0$

► **Conditional**

```
if (t[m]==v) return m;
```

$t_0[m_0] = v_0$ is consistent with the constraint store
so take the if part

$CSP \leftarrow CSP \wedge t_0[m_0] = v_0$

► **Complete execution path p whose constraint store**

C_p is:

$C_{pre} \wedge l_0 = 0 \wedge u_0 = 7 \wedge m_0 = 3 \wedge t_0[m_0] = v_0$

Binary search (5)

Return statement has been reached

- ▶ add negation of post condition and link JML \result variable with returned value m_0

```
\result!==-1 ==> t[\result] == v) &&
(\result== -1 ==> \forall int k;
                    0<=k<t.length; t[k] !=v)
```

$$\mathbf{m_0! = -1} \wedge \mathbf{t_0[m_0]! = v_0} \vee$$

$$\mathbf{m_0 = -1} \wedge (\mathbf{t_0[0] = v_0} \vee \mathbf{t_0[1] = v_0} \vee \dots \vee \mathbf{t_0[6] = v_0})$$

- ▶ solve the CSP

There is **No solution** so the program is **correct** along this execution path

Go back to conditional **if (t[m]==v)** to explore the *else* part

Binary search (5)

Return statement has been reached

- ▶ add negation of post condition and link JML \result variable with returned value m_0

```
\result!==-1 ==> t[\result] == v) &&
(\result==-1 ==> \forall int k;
                  0<=k<t.length; t[k]!=v)
```

$$\mathbf{m_0! = -1} \wedge \mathbf{t_0[m_0]! = v_0} \vee$$

$$\mathbf{m_0 = -1} \wedge (\mathbf{t_0[0] = v_0} \vee \mathbf{t_0[1] = v_0} \vee \dots \vee \mathbf{t_0[6] = v_0})$$

- ▶ **solve the CSP**

There is **No solution** so the program is **correct** along this execution path

Go back to conditional **if (t[m]==v)** to explore the **else** part

► Dedicated solvers

- **ad-hoc simplifier** : trivial simplifications and calculus on constants
- **linear solver** (LP algorithm) + **MIP solver**
- **Boolean solver** (SAT solver)
(Boolean relaxation of the **non linear** constraints)
- **CSP solver** : used if none of the other solver did find an inconsistency

► Prototype

- Solvers : Ilog CPLEX11 and JSolver4verif
- Written in **Java** using **JDT** (eclipse) for parsing Java programs

!! CPLEX is unsafe but Neumaier & Shcherbina
→ method for computing a certificate of infeasibility

Current prototype – On the fly validation : if **c** then ... else ...

- ▶ If **c** can be **simplified** into constant value “true” or “false”, select the branch which corresponds to **c**
- ▶ If **c** is linear
 1. add decision **c** in **linear_CSP**
 2. **solve linear_CSP**
 - ▶ if **linear_CSP has no solution**, condition **c** is not feasible for the current path
~> **choose another path**
 - ▶ if **linear_CSP has a solution**, we can't conclude anything on **complete_CSP**
~> **investigate both branches c and ¬c**

Basics on BMC

The CP
Framework

CPBPV

Overall view

Example

Implementation

Experiments

DPVS

FM Application

Discussion

Current prototype – On the fly validation : if **c** then ... else ...

- ▶ If **c** is NOT linear :
 1. **abstract** decision **c** and add it in **boolean_CSP**
 2. solve **boolean_CSP**
 - ▶ **boolean_CSP has no solution** \rightsquigarrow choose another path
 - ▶ if **boolean_CSP has a solution** \rightsquigarrow investigate both branches **c** and $\neg c$

Boolean abstraction

- hash-table of decisions : keys are decisions, values are Boolean variables
- sub-expressions are shared \rightarrow rewriting

Current prototype – On the fly validation : loops

Let c be the entrance condition

- if c is **trivially simplified** to “true” or “false”
 \rightsquigarrow **enter** or **exit** the loop
- if $\{c + \text{linear_CSP}\}$ is **inconsistent**
 \rightsquigarrow add $\neg c$ to the CSPs and **exit** the loop

In other cases, unfold loop **max** times:

- If **max** is **reached**
 \rightsquigarrow add $\neg c$ to the CSPs and **exit** the loop
- Else investigate **both** paths

We compared CPBVP with the following frameworks:

- ▶ **ESC/Java**, an Extended Static Checker for Java
↪ run-time errors in JML-annotated Java programs (static analysis of the code and its annotations)
- ▶ **CBMC**, a Bounded Model Checker for ANSI-C and C++ programs
↪ verification of array bounds (buffer overflows), pointer safety, exceptions, and user-specified assertions
- ▶ **BLAST**, a software model checker for C program (Berkeley Lazy Abstraction Software Verification Tool)
- ▶ **EUREKA**, a C bounded model checker which uses an SMT solver instead of an SAT solver
- ▶ **Why**, a verification platform which integrates provers (proof assistants such as Coq, PVS, HOL 4,...) and decision procedures (Simplify, Yices, ...)

3     int i = 0;
4     while (i!=t.length)
5         s=s+t[i]*t[i]
6         i =i+1;
7     return s;
```

- Using global constraint **alldiff**
- Solving **non linear** problems
- 66.179s for $n = 10$

- ▶ **CPLEX, the MIP solver**, plays a key role in all these benchmarks:
 - **Tritype**: the CP solver is never called
 - **Binary search**: there are only length calls to the CP solver (and much more calls to CPLEX) but almost 75% of the CPU time is spent in the CP solver
 - **Sum of squares**: 80% of the CPU time is spent in the CP solver

- ▶ We do not need the Boolean abstraction to capture the control structure of the program
 - **Use the CFG** and constraints **to prune the search space**

- ▶ **Depth first dynamic exploration of the CFG**
 - **Efficient** if the variables are instantiated early
 - **Blind searching:** post-condition becomes active **very late**

FM Application

Discussion

A **new search strategy** for verifying a restricted class of Java or C programs:

→ **Non sequential dynamic exploration of the CFG**

▶ **CPBPV: Depth first dynamic exploration** of the CFG

→ *Postcondition is used very late* because of the variables renaming

▶ **DPVS: Non-sequential exploration** of the CFG

→ *Starts from the postcondition and jumps to the locations where the variables are assigned*

Example

Algorithm

FM Application

Discussion

Non sequential dynamic constraint based exploration strategy

Why can we do it ?

Essential observation

When the program is in an SSA-like form, **a path can be built in a non-sequential dynamic way**

CFG does not have to be explored in a top down (or bottom up) way: compatible blocks can just be collected in a non-deterministic way

Example

Algorithm

FM Application

Discussion

Non sequential dynamic constraint based exploration strategy

Why does it pay off

- **DPVS starts from the post-condition** and dynamically collects program blocks which involve **variables of the post-condition**
- Collecting as much information as possible on a given variable
 - **enforces the constraints on its domain and reduces the search space**
- **Constraint solving is integrated with state exploration** to prune the state space as early as possible

Example
Algorithm

FM Application

Discussion

A small exemple

```
void foo(int a, int b)
int c, d, e, f;
if(a >= 0) {
    if(a < 10) {f = b - 1;}
    else {f = b - a;}
    c = a;
    if(b >= 0) {d = a; e = b;}
    else {d = a; e = -b;} }
else {
    c = b; d = 1; e = -a;
    if(a > b) {f = b + e + a;}
    else {f = e * a - b;} }
c = c + d + e;
assert(c >= d + e); // property p1
assert(f >= -b * e); // property p2
```

FM Application

Discussion

A small exemple(continued)

```
void foo(int a, int b)
int c, d, e, f;
if(a >= 0) {
  if(a < 10) {f = b - 1;}
  else {f = b - a;}
  c = a;
  if(b >= 0) {d = a; e = b;}
  else {d = a; e = -b;} }
else {
  c = b; d = 1; e = -a;
  if(a > b) {f = b + e + a;}
  else {f = e * a - b;}
  c = c + d + e;
  assert(c >= d + e); // property p1
  assert(f >= -b * e); // property p2
```

To prove property p_1 , select node (12), then select node (4)

→ the condition in node (0) must be true

$$\begin{aligned} S &= \{c_1 < d_0 + e_0 \wedge c_1 = c_0 + d_0 + e_0 \wedge c_0 = a_0 \wedge a_0 \geq 0\} \\ &= \{a_0 < 0 \wedge a_0 \geq 0\} \dots \text{inconsistent} \end{aligned}$$

A small exemple(continued)

Select node (8) \rightarrow condition in node (0) must be false

$$\begin{aligned} S &= \{c_1 < d_0 + e_0 \wedge c_1 = c_0 + d_0 + e_0 \wedge c_0 = b_0 \\ &\quad \wedge a_0 < 0 \wedge d_0 = 1 \wedge e_0 = -a_0\} \\ &= \{a_0 < 0 \wedge b_0 < 0\} \end{aligned}$$

Solution $\{a_0 = -1, b_0 = -1\}$

DPVS, Algorithm (scheme)

$S \leftarrow$ negation of *prop* % *constraint store*

$Q \leftarrow$ variables in *prop* % *queue of variables*

- While $Q \neq \emptyset$, $v \leftarrow \text{POP}(Q)$
 - **Search for a program block $PB(v)$ where v is defined**
PUSH($Q, \text{new_var}$), $\text{new_var} =$ new variables (\neq input variables) of $PB(v)$
 $S \leftarrow S \cup \{\text{definition of } v \text{ and conditions required to reach definition of } v\}$
 - IF **S is inconsistent, backtrack & search another definition** (otherwise the dual condition is cut off)
- IF $Q = \emptyset$ search for an **instantiation of the input variables (= counterexample)**

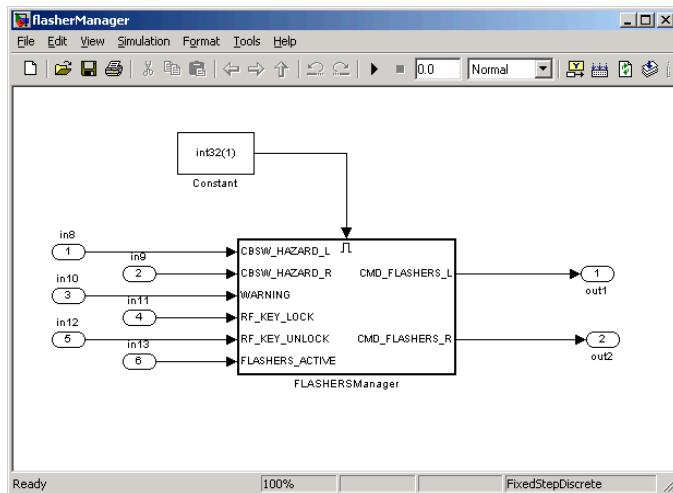

If no solution exists, DPVS backtracks.

- **A real time industrial application** from a car manufacturer (provided by Geensoft)
- **Flasher Manager (FM)**: controller that drives several functions related to the flashing lights

Purpose:

- to indicate a direction change
 - to lock and unlock the car from the distance
 - to activate the warning lights
-
- **Simulink model** of FM \rightarrow C function f_1

Discussion

Simulink model of FM \rightarrow C function f_1

- 81 Boolean variables (6 inputs, 2 outputs) and 28 integer variables
- **300 lines of code: nested conditionals including linear operations** and constant assignments

Piece of code:

```
and1_a=((Switch5==TRUE)&&(TRUE!=Unit_Delay3_a_DSTATE));
if ((TRUE==(and1_a-Unit_Delay_c_DSTATE)!= 0)) {
    rtb_Switch_b=0;
}
else {
    add_a = (1+Unit_Delay1_b_DSTATE);
    rtb_Switch_b = add_a;
}
superior_a = (rtb_Switch_b>=3);
```

- p_1 The lights should never remain lit.
- p_2 When the warning button has been pushed and then released, the `Warning` function resumes to the `Flashers_left` (or `Flashers_right`) function, if this function was active when the warning button was pushed
- p_3 When the `F` signal (for flasher active) is off, then the `Flashers_left`, `Flashers_right` and `Warning` functions are disabled. On the contrary, all the functions related to the lock and unlock of the car are maintained
- p_4 The `Warning` function has priority over other flashing functions

- Property p_1 : *The lights should never remain lit*

Property p_1 concerns the behaviour of FM for an **infinite time period**

→ p_1 is violated when the lights remain on for N **consecutive time period**

→ a loop (bounded by N) that counts the number of times where the output of FM has consecutively been true

Challenge: bound N **as great as possible**

Discussion

Program under test for Property:

```
1 void prop4(int d) {
2 //number of time where the left light has been consecutively true
3 int countL = 0;
4 //number of time where the right light has been consecutively true
5 int countR = 0;
6 //consider d units of time
7 for(int i=0;i<d;i++) {
8 //non-deterministic values of the inputs
9 L=nondet_in(); R=nondet_in();
10 LK=nondet_in(); ULK=nondet_in();
11 W=nondet_in(); F=nondet_in();
12 //call to fl() to simulate one pass through the module
13 fl();
14 if (outL)
15 //the left light has been consecutively true one more time
16 countL++;
17 else
18 //the left light has not been consecutively true
19 countL=0;
20 if (outR)
21 //the right light has been consecutively true one more time
22 countR++;
23 else
24 //the right light has not been consecutively true
25 countR=0;
26 }
27 //if countL and countR are less than d,
28 //then the lights did not remain lit
29 assert (countL<d && countR<d);
30 }
```

Exp. on FM](#)[Discussion](#)

- **DPVS, implemented in Comet**, a hybrid optimization platform for solving combinatorial problems
- **CPBPV***, an optimized version of CPBPV based on a dynamic **top down strategy**
- **CBMC**, one of the best bounded model checkers

Experiments were performed on a Quad-core Intel Xeon X5460 3.16GHz clocked with 16Gb memory
All times are given in seconds.

Discussion

Solving time:

N	CBMC	DPVS	CPBPV*
5	0.03	0.02	0.84
100	57.27	1.95	TO
200	232.19	3.45	TO
400	TO	4.66	TO

Pre-processing time:

N	CBMC	DPVS	CPBPV*
5	0.366	0.480	0.480
100	65.190	9.750	9.750
200	395.46	21.65	21.65
400	TO	50.90	50.90

Experiments on the binary search

Length	CBMC	DPVS	CPBPV*
4	5.732	0.529	0.107
8	110.081	35.074	0.298
16	TO	TO	1.149
64	TO	TO	27.714
128	TO	TO	153.646

- **DPVS and CBMC waste a lot of time in exploring the different paths**
- **CPBPV* incrementally adds the decisions taken along a path**
 - well adapted for the *Binary Search* program

- **Combining strategies**
- Using counter examples for **errors localization**
